ABSTRACT

This thesis describes the detailed design and implementation of a star cluster local area network among multiple Zenith Z-100 microcomputers. The Z-100s are linked together by the Concentrator, a server system consisting of a power supply, an iSBc 86/12A single board computer, and three BLC 8538 eight channel I/O expansion boards, through RS232c USART ports.

The local area network software consists of a server program resident in the Concentrator which provides the communication links between the Z-100s and the utility programs resident in each microcomputer. These utilities include file and message transfer (both point to point and broadcast), directory listing transfer, and online user identification. The program and utilities are written in JANUS/Ada, with assembly language subroutines for machine specific functions, and are designed to run with the CP/M-86 operating system.

ACKNOWLEDGEMENTS

I wish to thank Dr. Uno Kodres, Mr. Mike Williams, and Mr. Russ Whalen, without who this thesis would not have been possible.

I wish to thank my family and friends for being there when I needed you.

I wish to thank Kathleen, for whom I dedicate this thesis and all my accomplishments, for it is her love, patience, and understanding that makes it all possible.

I. INTRODUCTION

A. BACKGROUND

A critical requirement for today's office and laboratory environments is the sharing of expensive data and resources. A network of microcomputer workstations linked together can share data by transmitting files and messages between users and share peripheral resources such as printers by scheduling users in the most efficient manner. In the laboratory environment in particular, it is especially important and desirable to share data, experiments, and software development among lab members and to provide the means to distribute data to all members from a single source such as the professor or laboratory supervisor. Broadcast transmission from one workstation to all workstations of files or messages, or using one workstation as a 'bulletin board' to store messages over a period of time for access by all members, both serve this purpose. A testbed for research in data and resource sharing in the laboratory environment is a MULTIBUS based computer configuration which permits a single board computer to communicate with three input/output boards each containing eight RS-232 ports. This configuration serves as a concentrator for a star cluster local area network, which can connect up to twenty four RS-232 compatible devices.

This thesis is, in many ways, a companion to the thesis done by Lt. Cmdr. Robert Hartman and Capt. Alec Yasinsac,

[Ref. 1]. Their thesis involved the implementation of a prototype star cluster local area network of microcomputers connected to a Vax 11/780 computer over the ETHFRNET communications device. The Vax 11/780 system operating under the UNIX operating system provides access to the ARPANET wide area network. Their local area network is operated under the MS-DOS environment and involves the use of various protocols necessary for communications with ARPANET.

The aim of this thesis is to provide an efficient data communications environment limited to the local area network of 2-100 workstations running under the CP/M-86 operating system.

F. PROJECT DESCRIPTION

1. Proposed Capabilities

a. Local File Transfer

Any microcomputer should be able to transfer a file to any other microcomputer asynchronously. Additionally, any microcomputer should be able to 'broadcast' files to multiple microcomputers simultaneously.

b. Local Message Transfer

Any microcomputer should be able to transfer messages in the same manner as files, with the additional capability of having one microcomputer serve as a 'bulletin board' for the others.

c. Directory Transfer

Any microcomputer should be able to transfer a directory in the same manner as messages and files.

d. Online User Identification

Any microcomputer should be able to obtain a 'net status'; the identities of all currently active workstations in the network, at any given time.

2. Target Hardware

The proposed local area network consists of up to twenty four Z-100 microcomputer workstations connected via RS-232 communications ports to a central MULTIBUS based single board computer, which acts as a central switchboard to provide communications between the workstations.

3. Software

All the applications software for the microcomputers and the processing software for the single board computer acting as a switchboard has been written by the author for this thesis.

C. STRUCTURE OF THE THESIS

The majority of this thesis is the program code that implements the network. The accompanying text provides system description, design decisions, problems encountered, and operating and maintenance procedures. Chapter II describes the hardware of the system, Chapter III details the 8086 CPU, and Chapter IV explains the CP/M-86 operating system. A description of the JANUS/Ada language detailing useful

features, problems encountered, and lessons learned from the prospective of a newcomer to the language with reference to the full ADA language is provided in Chapter V. Chapter VI explains the design methodology and the details of the software implementation with descriptions of each major module.

The appendices provide the program code, user and maintenance manuals, a glossary, and a bibliography.

II. HARDWARE

A. THE 86/12A SPC

The 86/12A single board computer is a complete computer system on a single printed circuit board. It includes a 16 bit 8086 CPU, 32K, expandable to 64K, bytes of dynamic RAM, a serial communications interface, three programmable parallel I/O ports, programmable timers, priority interrupt control, MULTIBUS interface control logic, bus expansion drivers for interface with other compatible MULTIBUS expansion boards, and up to 16K bytes of ROM. Table 2.1 lists the possible I/O port addressing assignments.

TABLE 2.1

00D8	8251A	write: Data (J2)
or 00DC	USART	read: Data (J2)
00DA		write: Mode/Command
or 00DE		read: Status

The 8538 Eight Channel Communication Expansion Board is a fully programmable synchronous/asynchronous serial communication channel with RS232C interfaces connected to IC2651 USARTs for serial communications with other devices, and is compatible with the MULTIBUS system. The total address space for each board is 64, or 40 Hex, locations. Each board has a base address that is selectable by DIP switches on the board and is set to 0100 Hex for this implementation. Disregarding the base address for the moment, board 1 would start at 0, board 2 at 40 Hex, and so on. The primary locations of interest are the data register, the status register, the mode register, and the command register. These locations are 0-3 for port 0, 4-7 for port 1, and so on up to 20 Hex for the

eight USARTs. The remaining address locations are for interrupt handling and are not used in this implementation. The port addressing is shown in Table 2.2.

B. THE Z-100

The Zenith Z-100 is a dual processor 8085/8088 computer with either one or two 5.25 inch floppy disk drives and one Winchester hard disk drive providing up to 750K bytes of directly addressable RAM. It is powered by a 5MHZ clock.

The Z-100's main circuit board contains the 8085 and 8088 CPUs and the S-100 IEEE 696 bus. It has the capacity for 192K bytes of memory. Also contained on the main board is

the 8041A keyboard processor, two RS-232 serial interfaces and connectors, one parallel interface and connector, and the video circuit board interface.

The video circuit board contains the CRT controller and supports a bit mapped video system with up to three banks of 32K byte memory devices for red, green, and blue.

The floppy disk drive controller, which can support up to four 5.25 inch and four eight inch drives, and the Winchester disk controller are on separate cards and are each connected to one of the slots of the S-100 bus.

Other hardware features of interest include: the 8259A Programmable Interrupt Controller, the 68A21 Peripheral Interface Adapter, the 8253 Programmable Interval Timer, and the 2661 Enhanced Programmable Communications Interface. The Z-100 has two serial ports, labeled J1, the printer port, and J2, the modem port, both of which are connected through the 2661 interface.

III. THE CENTRAL PROCESSING UNITS

A. THE 8086

The 86/12A single board computer uses the INTEL 8086 microprocessor for its CPU (Central Processing Unit). The 8086 is a high performance, general purpose 16 bit microprocessor. It has a 20 bit address bus, allowing access to a full megabyte of memory. Since the largest register in the 8086 is only 16 bits, it uses segmentation to form 20 bit addresses from the four 16 bit address registers; the CS (Code Segment), the DS (Data Segment), the SS (Stack Segment), and the ES (Extra Segment). These four registers reside in the BIU (Bus Interface Unit).

The EU (Execution Unit) contains nine 16 bit registers interfaced to a 16 bit data bus, four of which are byte or word addressable; the AX (AH, AL), BX, CX, and the DX, and four of which are only word addressable; the SP (Stack Pointer), the BP (Base Pointer), the SI (Source Index), and the DI (Destination Index). The remaining register is the flag register which has nine usable bits; Carry, Parity, Auxiliary Carry, Zero, Sign, Trap, Interrupt, Direction, and Overflow. Lastly, there is one 16 bit IP (Instruction Pointer) register.

The BIU and the EU operate asynchronously in the 8086. Additionally the BIU has an instruction object code queue. These two features combine to virtually eliminate instruction fetch time. By fetching the next instruction, while the

previous is being decoded and executed, and loading it in a queue, the 8086 ensures that there is always an instruction ready the instant it is required. Only when a jump instruction causes the current instruction sequence to be changed, is the instruction queue flushed.

B. THE 8088

The Z-100 uses both the 8 bit 8085 CPU and the 16 bit 8088 CPU. The 8088 is the processor of interest to this thesis. The 8088 is compatible with the 8086 and is (to the programmer) virtually identical. In particular, the 8088 programmable registers and addressing modes are exactly the same. The significant difference is that it has an 8 bit data bus versus the 16 bit data bus of the 8086.

The differences between the two CPUs are evidenced in execution times. The 8088 has a four byte instruction queue compared to the six byte queue in 8086. This results in more code fetches per instruction and slows down instruction processing. The 8 bit data bus requires the 8088 to take two bus cycles whenever the 8086 would have used only one to fetch 16 bits of data. All other execution time values are identical.

IV. THE OPERATING SYSTEM

CP/M-86 is an operating system designed by Digital Research for the 8086 and 8088 sixteen bit microprocessor. It contains three program modules: the CCP, the BDOS, and the BIOS. Entry to the BDOS is provided through the reserved software interrupt #224 (E0 Hex), while entry to the BIOS is provided by either a jump vector located at offset 2500 Hex from the operating system base, or by use of the BDOS function #50. For this implementation, only entry to the BDOS was required. BDOS functions were used for keyboard input, console output, and file operations. Table 4.1 lists each function call used with entry and return parameters indicated.

Access to files in CP/M-86 is achieved by use of the File Control Block (FCB) whose format is shown in Table 4.2. Each FCB is identified by specifying its relative offset from the data segment register. When reading from or writing to a file, BDOS uses sequential 128 byte records to transfer information from the file into memory at the current Direct Memory Address (DMA) and vice-versa. The DMA can be specified by the user as the relative offset from a specified or default DMA base.

CP/M-86 uses one directory entry per 16K bytes of file data, termed an extent. During sequential reads and writes the "cr" field of the FCB is incremented for each 128 byte record until the next extent is required. Unless no more

```

record or directory space exists, the next extent is automatically opened. Then the "cr" field is reset to zero and a new directory entry for the new extent is created.

When directory searches are made, the 128 byte record containing the matched entry is placed in memory at the DMA address. For files with multiple extents, the first directory entry is matched. There are four entries per record.

The location of the matched entry is computed by multiplying the offset returned by the function call by 32 and adding it to the DMA address.

DDT86 proved to be an invaluable tool to the development of this thesis. DDT86, a utility program supplied with CP/M-86, is a dynamic, interactive debug and test program for the CP/M-86 environment. It worked excellently with both the high level JANUS/Ada code and the assembly language subroutines interfaced with the high level code. DISASM86, the disassembler provided with the JANUS/Ada system, presented the high level code in its post-compiled assembly form which could then be debugged using DDT86. Completion of this thesis would not have been possible without the use of DDT86. Its only drawback was a tendency to 'slow' down a program to the point where it would work under DDT86, but would fail in the real time environment outside DDT86, which caused understandable confusion.

Additional detailed information about CP/M-86 can be found in [Refs. 2 & 3].

V. THE PROGRAMMING LANGUAGE

ADA is the Department of Defense's mandated language for embedded computer systems. According to DOD directive 5000.31 [Ref. 4], "all mission critical defense systems that enter advanced development status after 1 Jan 84, or that enter full scale development after 1 Jul 84" will be coded in ADA. Introduced in its final form in September 1980, ADA has inspired much activity, discussion, and debate. Due to its large size and complexity, commercial compilers are only now becoming available.

JANUS/Ada, an implementation designed for microcomputers, was chosen for this project because of its availability, and its suitability to systems programming tasks. Although not fully ADA compatible in its treatment of strings, use of inline ASM statements, or the data type Byte, and lacking the capability for exception handling or concurrent tasking, research in the JANUS/Ada implementation should prove invaluable to the effective use of the full language itself; a language destined to be the Department of Defense's standard for embedded systems.

This author's programming experience prior to this project was limited to only the basics of Pascal and Assembly languages. According to Bernard [Ref. 5], my experiences can best be described by:

While people who have a high level language should be able to learn what is referred to as 'the Pascal subset' of ADA with about four weeks of full-time study, many educators report that it takes six months to learn to make effective use of the language.

Also required are a firm knowledge of structured programming and software engineering. It is clear, however, that the ADA designers were correct to base the language syntax on Pascal, a language designed and recognized as the standard to teach students about structured programming.

The most impressive and useful control structure in ADA is the 'Loop' statement. The ability to exit a loop wherever and whenever desired, combined with the traditional constructs of 'For' and 'While', makes the Loop statement applicable to an almost infinite set of design structures and truly supports the concept of structured, easy to read programming. This feature alone separates ADA's control structures from Pascal, Cobol, Fortran, and others.

JANUS/Ada's resident assembly language interface is also extremely useful. Routines that require high speed and efficiency or specific bit/byte manipulation could be coded in assembly language and called from the high level program. This feature answers the traditional systems programmer's need for control of, and access to, the specific machine. The ease with which assembly code could be used in conjunction with high level JANUS/Ada code was very important to this project. Almost all of the I/O and file operations required in the programs were coded in assembly language. This was

partly for speed and efficiency and partly because many of the I/O and file operations built into JANUS/Ada would not work (for reasons undiscovered) after a single call to the CP/M-86 operating system was issued.

ADA's use of packages as the unit of program modularity is an important step in the evolution of structured programming languages. Packages contain data, procedures, and/or functions that for reasons of a particular program's modular design are grouped together to form a unit. A program's various packages are then linked together for execution. Packages support efficient modular design and allow for the effective construction of program libraries of frequently used routines and data structures for programmers to use. Data and routines are made available to users and other packages through Specifications, which provide all the necessary information for their use while hiding the details of the implementation, thus supporting the principle of information hiding.

Packages are also the main instrument of separate compilation, which is becoming a requisite feature of modern programming languages. Unless the vehicle for communication between linked packages, the specification, is changed, modifying a single package requires only its recompilation and not the recompilation of packages referencing it or referenced by it.

Separate compilation is particularly important in JANUS/Ada, and by extension, ADA, because the size and complexity of the language dictates that compilers for it be also large, complex, and relatively slow. This causes software development problems of time and storage.

The compiler itself, while a bit slow, provided helpful compile and run time error checking. Because ADA (and JANUS/Ada) is a strongly typed language, an efficient compiler should be able to detect a majority of errors at compile time, thereby saving development time. The JANUS/Ada compiler does so and even corrected certain syntax errors itself, producing a working program. While it is, in general, difficult to produce simple yet completely explanatory error messages, the JANUS/Ada compiler does a noteworthy job.

[Ref. 6], provided with the JANUS/Ada system, was more than adequate overall. It was not sufficient (and admitted so) to teach the JANUS/Ada language, but its manuals and appendices on the compiler, the assembler, the linker, etc. were first rate. Its description of library packages was also very helpful. [Ref. 7] provided all the necessary information to begin learning ADA in a very practical and concise manner.

VI. THE IMPLEMENTATION

A. METHODOLOGY

This author's inexperience with the hardware, the programming language, and software development of this nature (systems programming) and this scope (larger by far than anything attempted before), necessitated complete decomposition and modularization of the problem. The principle of top-down programming was used as the problem was broken into smaller and smaller functional elements until the most basic functions were identified. Such functions as basic input and output, opening and closing files, and interfacing assembly language with JANUS/Ada were coded and tested. These functional entities were combined in a building block manner, until larger and more complex functions such as character transfer and file transfer between two Z-100 were completed. Eventually, interface with the concentrator was achieved as the system began to take shape. The system was finished when the highest levels of the program hierarchy were finally completed and all the decomposed modules of the problem were coded, tested, and linked.

B. SYSTEMS DESIGN

The problem of designing a star cluster local area network may be decomposed into two parts:

1. Programming the Concentrator.
2. Programming the Z-100.

1. The Concentrator

The role of the concentrator is to process network commands from the Z-100s, establish and maintain data communication connections, and route commands and data between Z-100s. The network principle of 'circuit switching' is implemented to route the commands and data. The Concentrator establishes and maintains data communication connections between the source and destination Z-100(s) until the entire user process or 'circuit' is completed.

Within the Concentrator the problem may be further decomposed into two parts. The Concentrator must poll all the ports in the network upon initiation and after each connection is terminated, to determine if any Z-100s are ready to participate in the network, and it must establish and maintain data communication connections.

Currently the Concentrator is equipped with three 8538 BLC expansion boards for a total of 24 available ports. Network expansion can be accomplished by adding more expansion boards and changing the value of the constants 'machno' and 'boardno' accordingly.

The Concentrator polls each port looking for the 'active' signal from a Z-100. If there is no response after a finite period of time, the Concentrator moves on to the next port. If the 'active' signal is received, the Concentrator stops and determines if there are processes waiting for this Z-100 from other Z-100s. If there are no

processes waiting, the Concentrator decodes the subsequent command information from the polled Z-100, and establishes the data communication connection for the requested process.

If there are processes waiting for the Z-100 being polled, the Concentrator decodes the first process in line, contacts the sender of that waiting process, and establishes a data communication connection for the transferral of the waiting process. Upon transfer of the first waiting process, or if the sender is no longer active, the waiting process is destroyed and the Concentrator returns to the polled Z-100 in order to decode the subsequent command information, and establish the data communication connection for the original requested process.

The Concentrator will satisfy at most one waiting process per polling cycle; a polling cycle is one loop around the network of twenty four ports. If there is more than one process waiting in the queue for a particular Z-100, the one which is first in the queue (first come, first served) is serviced during one polling cycle. The next queue element is serviced during the next polling cycle and so on until there are no more waiting processes.

There are two methods of transferring commands and data in this design:

1. Direct Z-100 - to - Z-100.
2. Broadcast to all active Z-100s in the network.

The Z-100 transmits to the Concentrator the transferring method and the Concentrator uses that method for all file, message, or directory transferral.

Once a data communication connection is established, the Concentrator acts as a transparent pathway, transferring commands and data without regard, and looking only for a sequence of four end of process codes (0F1h) from the destination Z-100(s). Receiving this sequence, the Concentrator terminates the connection and resumes polling where it left off. The Concentrator polls in an endless loop, stopping only to process requests from the ports of the network.

For single transferrals, error checking is performed by the sending and receiving terminals. For broadcast transferrals, the Concentrator performs the error checking between itself and the receiving terminals while the sender performs error checking between itself and the Concentrator.

If a data communication connection cannot be established, the record data structure 'connection' containing fields for source, destination, and process is queued in a FIFO queue implemented as an array of records. The queue is limited to one process per source Z-100 per destination Z-100 and is limited to message and file processes. It is this queue that the Concentrator checks after receiving the 'active' signal from any Z-100 during the polling process.

2. The Z-100

The role of the Z-100 is to communicate with the user and the Concentrator for the purposes of processing network application programs. Commands are transmitted from the user to the Concentrator, enabling the establishment of the proper data communication connection. Then the source Z-100 transmits commands and data to the destination Z-100(s).

The network applications consist of three Z-100 to Z-100 functions; file transfer, message transfer, and directory transfer, and one Z-100 to Concentrator function; net status. Within each Z-100 to Z-100 function is a sending process and a receiving process. It is these processes that serve as the network unit of execution. The source Z-100 initiates a process, the Concentrator establishes a connection with the destination Z-100(s), and maintains the connection until the process is finished. Then the next process is initiated and so on.

Both the Z-100 and the Concentrator use the record data structure 'connection' to establish data communication connections. 'Connection' contains three fields; 'source', 'destination', and 'process'.

```
TYPE conctn IS
  RECORD
    source: byte;
    destination: byte;
    process: byte;
  END RECORD;
```

The source Z-100 creates the connection record and transmits it to the Concentrator where it is decoded and the proper pathway is established. When the destination Z-100(s) acknowledge the connection, communication begins. If the connection can not be established, the connection record is stored by the Concentrator in the queue. Upon completion of the process, the connection record in the Concentrator and the Z-100 is destroyed.

The Z-100 network application programs are menu driven and implemented in an infinite loop. The Z-100 transmits an 'active' signal to the Concentrator and waits to be polled by the Concentrator. When polled the user is told if there is a process waiting for him/her and is requested to receive that process. Then the user selects a process from the menu and the Z-100 and the Concentrator carry out that process as described above. After process completion, control is returned to the infinite loop which transmits an 'active' signal again, waits to be polled, asks for user input, and so on until the user terminates the loop with "control x".

3. Command and Data Communication

A main concern of this thesis is efficient data communications. Fast, error free transmission of commands and data along the data communication connection for both point to point and broadcast, is achieved by an immediate echo method implemented in JANUS/Assembler language for

CP/M-86. The method uses the fact that instruction execution time is much shorter than data transmission time and attempts to minimize wait times as much as possible. All bytes received by any procedure are immediately echoed and the received echoes are then checked for error.

The sending procedure transmits a byte and then waits for an echo from the receiver. It compares the echo with the transmitted byte. If an error is detected, the sending procedure, depending on its function, either retransmits immediately or transmits an error code followed by the retransmitted byte. (For the broadcast method the byte is transmitted to all destination Z-100s before the echoes are received and compared.)

The receiving procedure receives a byte and then immediately echoes it before proceeding to process the received byte. If an error code is received when it returns to receive the next byte, the receiver erases the byte in error and returns to receive the retransmitted byte.

The method is sufficiently general in design to handle more difficult errors than just errors in data bytes transmitted from the sender to the receiver. For instance, the method will detect and correct errors in the echo transmitted back to the sender. This is a particularly insidious error because the receiver actually received the correct data byte, but the sender doesn't think so and sends out an error code or retransmits the data byte. The method

will also correct multiple errors such as when a data byte is transmitted in error and so is the subsequent error code. The sender will stay with the error until it is corrected to its satisfaction and the receiver will always know how many received data bytes are in error and how many to erase. This is true even when a procedure is both a sender and a receiver as in the procedure 'Setup'. Additionally, every receiving procedure has a finite waiting period to ensure the final byte and echo are received properly.

4. Design Considerations

a. Assembly Language

JANUS/Assembler combined with CP/M-86 BDOS function calls was used for all I/O subroutines except for the display of non-conditional strings to the user. This was decided because of the need for speed, efficiency, and implementation of the data communication connection. Because of an undiscovered bug in JANUS/Ada, use of CP/M-86 function calls invalidated the perfectly adequate built in JANUS/Ada file operation routines. Thus these functions too were implemented in JANUS/Assembler with CP/M-86 BDOS function calls.

b. Memory Management

The Concentrator programs are estimated to occupy 25K of the 64K bytes of memory in the Concentrator. Due to the limited size of the queue for waiting processes, and to the use of message switching as the principle of network

communication, circuit management was deemed not necessary and was not implemented.

c. Process Coordination

The network processes do not use interrupts for coordination. Processes execute sequentially until communication is required. This communication is designed such that when, say, a sender is waiting to transmit specific commands or data, the receiver will eventually 'rendezvous' (although not in the concurrent sense) and the proper receiving procedure will receive and process the transmitted commands or data. When necessary, such as when polling ports, processes will wait a finite period of time and then move on. Occasionally, a process will stop until the receiver tells it to continue. Blocks of data are identified by end of block codes (0FFh), and codes are transmitted to tell the receiver whether or not this was the last block. Special care was exercised in the implementation to ensure that deadlock did not occur ie: both processes expecting to receive or to transmit.

The Concentrator, which is both a receiver and a sender, employs the same design principles when polling ports, checking or updating queues, and establishing data communication connections. Once a connection is established, it treats everything as a block of data, moving on only when a sequence of four end of process codes (0F1h) from the destination Z-100(s) is received.

d. The Data Type Byte

Use of the JANUS/Ada predefined data type Byte, which is not ADA standard, was necessitated by the network requirement to transmit all eight bits of each data byte and the method used to transmit and receive commands and data. The data type Character with only seven bits, and the data type Integer, which is not well suited for the manipulations needed for transmission, were not sufficient to represent the data byte used in command and data communication in this implementation.

C. SYSTEM EXECUTION

The implemented network application programs are menu and command driven. At program start and after each process, the 'active' signal is transmitted to the Concentrator and the program waits to be polled. When polled the program is informed if there are processes waiting for this Z-100. If there are processes waiting, the user is asked to receive them. Then the user is presented with the following menu:

```
CTRL_S = SEND FILE
CTRL_R = RECEIVE FILE
CTRL_T = SEND MESSAGE (TALK)
CTRL_I = RECEIVE MESSAGE (LISTEN)
CTRL_P = SEND DIRECTORY
CTRL_G = RECEIVE DIRECTORY
CTRL_W = GET NET STATUS (WHO)
CTRL_B = RECEIVE BULLETIN BOARD
OTHERS = RECHECK FOR INCOMING FILE OR MESSAGE
```

The user makes his or her selection and is placed in the appropriate environment. Upon completion of each process,

the user can press any key and be returned to the main menu or pause indefinitely. Upon return to the main menu, the user is given the option of exiting using "CTRL_X" or continuing "ANY KEY".

To send a file, the user is prompted for the disk drive, file name, and file type of the file he wishes to send. The user's input is displayed as he types and invalid entries (those characters not permitted in file names and file types by CP/M-86) are flagged. A sample entry might look like this:

```
FN.FT: myfil? INVALID ENTRY
myfil_
```

Once entered the file name and type are capitalized in accordance with CP/M-86 format and the user's choice is displayed for confirmation:

```
C: MYFILE.TXT IS SELECTED. PRESS RETURN TO CONFIRM,
ANY OTHER KEY TO RESELECT.
```

Upon confirmation, the user is prompted for the destination terminal (or broadcast) and the source terminal. Then a search is made for the file. If it can not be found an error message is displayed and the user is given the opportunity to reselect. If it is found the file is opened. Then, if the destination is active, the transmission begins. Otherwise, a message indicating that the destination was inactive is displayed and the user is returned to the main menu.

The file is sent in successive 128 byte data blocks until end of file is reached. After each data block, the sender

indicates to the receiver whether or not end of file has occurred and stops until the receiver tells the sender to continue. Once the file is sent, it is closed and the user is returned to the main menu.

To receive a file, the user is prompted as above for drive, file name, and file type. Upon confirmation, the file named by the user is first deleted and then created. This is done to ensure no errors occur during the create operation and has the effect of overwriting the file if the user chooses a file already on the disk. After creating the file, reception begins.

The file is received in 128 byte data blocks and after each block is written to disk, end of file is checked and the sender is told to continue. Once the file is received, it is closed and the user is informed of the number of bytes received. Error messages are displayed if there is no more disk space or directory space on the receiver. The user is then returned to the main menu.

To send a message, the user is prompted to begin typing and told that the maximum message length is 1600 characters. All characters entered except "CTRL_Z" are sent. The message is organized in a 'page' format of twenty lines with 80 characters each. A limited correction capability is included, consisting of typing "backspace" or "CTRL_E" and then retyping the character. However, the error, the backspace or CTRL_H, and the retyped character all count as typed

characters. The message format consists of twenty lines of 80 'keystrokes' each. Users must keep this in mind when typing.

"CTRL_Z" stops message typing and "CTRL_S" sends it. Any other key allows the user to retype the message. After "CTRL_S", the user is prompted for the source and destination (or broadcast) terminals as above. If the destination is active, the message is transmitted as one data block with appropriate end of message codes. The user is returned to the main menu upon completion of the transmission.

To receive a message, the user types "CTRL_L" from the main menu and reception occurs. The message is displayed and the user is informed of end of message and the number of bytes received. The user is then returned to the main menu.

To send a directory, the user is prompted for the disk drive for which directory he wishes to send. (Presumably in response to a request.) After confirmation, the user is prompted for the source and destination (or broadcast) terminals as above. The directory of the selected drive is then searched for the CP/M-86 wild card file name and type (?????????.???) causing the entire directory to be matched. Each directory entry is placed in the transmission data block until there are eight directory entries for a total of 128 bytes. If the destination is active this data block is then transmitted, preceded by the disk drive, with a code indicating whether or not end of directory has occurred. If there

are no files on the selected disk a "NO FILES ON SELECTED DISK." string is transmitted to the receiver. The user is returned to the main menu upon completion of the transmission.

To receive a directory, the user is prompted as above for drive, file name, and file type in which he wishes to store the incoming directory. Upon confirmation, the file named by the user is first deleted and then created. This is done to ensure no errors occur during the create operation and has the effect of overwriting the file if the user chooses a file already on the disk. After creating the file, reception begins.

The drive of the directory is received first and then the first 128 byte data block. After checking for end of directory, the eight directory entries of the data block are displayed and the user is asked if he wishes to save them on file. Each data block is received the same way. Those data blocks the user wishes to save are written to disk and the rest are discarded. Error messages are displayed if there is no more disk space or directory space on the receiver. When end of directory is reached the reception is ceased, the file closed, and the user returned to the main menu. The file created during this operation should be edited by the user as it may contain characters from each directory entry that are not printable.

To obtain a current net status of the active terminals in the network, the user is prompted for the source and destination terminals as above with the exception that he must enter his terminal for both source and destination. Upon confirmation, a list by number of all active terminals is displayed and the user is returned to the main menu.

Messages are sent the bulletin board, if it is active, by selecting machine #24 when prompted. The bulletin board is 'read' by selecting CTRL_B at the main menu. If the bulletin board is active, all the current messages are transmitted, in 128 byte blocks, and stored in a user specified file, chosen in the same manner as the receiving of file transfers. This file can then be perused at leisure. The bulletin board can hold up to twenty messages of 1600 bytes each. The twenty-first message replaces the first message and so on.

VII. CONCLUSIONS

The research objectives of this thesis; coding in JANUS/Ada, allowing single or multiple transfers of files, messages, and directories, and sharing of local resources in a laboratory environment, were satisfactorily completed. However, the complete testing and demonstration of the network in operation was not achieved.

The utilities resident in the Z-100 workstations were completely and satisfactorily tested. So too were the establishment of data communications connections and data transfer through the concentrator of files, messages, and directories from a single Z-100 to another single Z-100 and to multiple (two) Z-100s. The polling mechanism in the concentrator, obtaining net status, and the storing of messages in and retrieval from the bulletin board were also satisfactorily tested.

Remaining to be tested are: the mechanism for the storing of processes for which a connection could not be established and the mechanism for placing and servicing the waiting processes in the queue. Finally, the testing of the entire system of 23 Z-100 workstations and one Bulletin board under all conditions and loads awaits demonstration.

In sum, each module and subroutine was separately compiled and tested, functional integration of parts of the

system were tested and satisfactorily demonstrated, but the complete integration of the entire network was not accomplished.

To achieve final system integration and completion of the network, it is recommended that a two step testing process be conducted. First, set up, under laboratory conditions, a small network consisting of seven Z-100 workstations and a bulletin board using one full 8538 expansion board. In this set up, fully test the package 'Poll' in various experimental situations to ensure that it handles all circumstances as designed and that the queue operations function properly. Second, establish the full network and test it in an operational environment under all conditions of load and function.

The experience of coding this thesis was very challenging and stimulating. Despite my very limited programming background in Pascal, I was able to quickly grasp the fundamentals of Janus/Ada and begin coding small test procedures. As the requirements for the project became clearer, coding intensified and increased in size and scope.

However, I found myself habitually using Pascal or Pascal-like structures. I was tapping very little of the power and richness of Janus/Ada. For instance, I would use

```
IF condition THEN  
    EXIT;  
END IF;
```

rather than

```
EXIT WHEN condition;
```

to exit loops. Features such as attributes, subtypes, derived types, and ranges were used very little in the beginning. Additionally, the nature of the project precluded working with real or fixed point types and all their features plus many of the built in or provided library subroutines.

It was in the use of the LOOP statement that I began to explore the full power of Janus/Ada over Pascal. I quickly learned to tailor the loop statement to achieve any effect I desired and found it extremely useful in structuring my programs. Gradually, in this and other structures, I began to use Janus/Ada more elegantly and to remove 'Pascal' from my coding, although some always remained.

Surprisingly, the grouping of programs, subroutines, and data into packages and the linking together of these packages into a single program proved very easy to assimilate. The understanding and use of the scope and visibility rules, however, was harder to grasp. As a result, the use of selected components for naming variables in one package while in another package, or the use of private types were not implemented.

The first real problems occurred in the use of input and output, usually the hardest part of any language. For

reasons previously explained, assembly language subroutines interfaced with Janus/Ada programs were used for virtually all input and output. My previous assembly language experience was with 8080 mnemonics, but the use of 8086 mnemonics was easy to learn because I was required to use only those instructions that had counterparts in 8080 and I only had to learn the new register and addressing schemes. However, the interface with Janus/Ada proved extremely difficult to master. It took much trial and error to realize exactly how the parameters were passed and returned from the assembly language subroutine and how the stack was manipulated when the subroutine was called.

Lastly, the requirements of data communication were the hardest to implement. The idea of two programs executing on two different machines and communicating with each other was entirely new. The errors that resulted were difficult to diagnose and correct. In my previous experience, programs very rarely encountered infinite loops; either they didn't work correctly or they produced wrong answers, but they always finished. In data communication, infinite loops were frequent as the programs deadlocked waiting for the other to stop or start communicating. The synchronization of procedures and routines in programs executing in parallel, so that procedures that needed to communicate would 'meet' at the right place and the right time, was the most difficult aspect of coding this thesis.

This thesis demonstrated the following capabilities. First, the ability of JANUS/Ada, and by extension, ADA, to effectively and efficiently perform complex data communication and network functions. Second, the viability of clustering microcomputers for the sharing of resources and the enhancement of data communications and transfer. Finally, the ability of an inexperienced programmer to learn ADA and use it in the solving of complex computer problems.

APPENDIX A
USER'S MANUAL

A. GETTING STARTED

The system is designed to operate on the Zenith model 120 microcomputer connected to the concentrator in the NPS microcomputer lab. The file Xfermain.cmd should be on the hard disk and the CP/M-86 operating system should be selected.

B. SYSTEMS OPERATION

The command 'xfermain' will place the user in the network. The first message should be:

'WAITING TO BE POLLED.'

Note: System messages are always in uppercase. This means that this Z-120 is waiting to be recognized by the network. A wait of some time may result if the system is busy. If the wait becomes excessive, see the system's maintenance personnel. When recognized, the next message should be:

'CHECKING FOR INCOMING FILE OR MESSAGE.'

If there is an incoming file or message, the user will be asked to receive it prior to continuing with the user's request.

After the incoming data has been received or if there is no data, the following menu will be displayed:

```
CTRL_S = SEND FILE
CTRL_R = RECEIVE FILE
CTRL_T = SEND MESSAGE (TALK)
CTRL_L = RECEIVE MESSAGE (LISTEN)
CTRL_P = SEND DIRECTORY
CTRL_G = RECEIVE DIRECTORY
CTRL_W = GET NET STATUS (WHO)
CTRL_B = RECEIVE BULLETIN BOARD
OTHERS = RECHECK FOR INCOMING FILE OR MESSAGE
```

Selecting the proper entry will place the user in the desired environment.

C. SENDFILE

Once in Sendfile, the command messages are self explanatory. The program forces the input of a CP/M-86 acceptable file name and file type, but the user must ensure that the file exists on the selected disk. An error message will result otherwise. The next step is selecting the destination machine (numbered 01 through 23) or broadcast to all (number 00). If the requested destination is not presently in the network, the request to send a file will be queued along with the intended destination. Some delay may occur in the sending of a file if the file is very large or the network is very busy. Excessive delay should be referred to the systems maintenance personnel.

D. RECEIVEFILE

Once in Receivefile, the command messages are self explanatory. The program prompts for a file name and file type for the incoming data. It forces the input of a CP/M-86 acceptable file name and file type, but the user must ensure that sufficient space exists for the file on the selected disk. An error message will result otherwise. Some delay may occur in the receiving of a file if the file is very large or the network is very busy. Excessive delay should be referred to the systems maintenance personnel.

E. TALKING

Once in Talking, the command messages are self explanatory. Message length is 1600 characters organized in 20 lines of 80. Errors can be corrected using backspace or 'control h', but each keystroke counts towards the 1600. The next step is selecting the destination machine (numbered 01 through 23), broadcast to all (number 00), or bulletin board (number 24). If the requested destination is not presently in the network, the request to send a message will be queued along with the intended destination. Some delay may occur in the sending of a message if the message is very large or the network is very busy. Excessive delay should be referred to the systems maintenance personnel.

F. LISTENING

Once in Listening, the message is received immediately and displayed as typed.

G. WHOS_THERE

Once in Whos_there, the user is prompted to enter his machine number as the destination. Then the net status is received.

H. RECEIVE_DIR

Once in Receive_dir, the command messages are self explanatory. The program prompts for a file name and file type for the incoming data. It forces the input of a CP/M-86 acceptable file name and file type, but the user must ensure that sufficient space exists for the file on the selected disk. An error message will result otherwise. The user may save only those directory entries he desires. Some delay may occur in the receiving of a directory if the directory is very large or the network is very busy. Excessive delay should be referred to the systems maintenance personnel.

I. PRESENT_DIR

Once in Present_dir, the command messages are self explanatory. The user is prompted to select the destination machine (numbered 01 through 23) or broadcast to all (number 00). If the requested destination is not presently in the network, the request to send a directory will not be queued and is destroyed. Some delay may occur in the sending of a directory if the directory is very large or the network is very busy. Excessive delay should be referred to the systems maintenance personnel.

J. BULLBRD

Once in Bullbrd, the command messages are self explanatory. The program prompts for a file name and file type for the incoming data. It forces the input of a CP/M-86 acceptable file name and file type, but the user must ensure that sufficient space exists for the file on the selected disk. An error message will result otherwise. Some delay may occur in the receiving of messages from the bulletin board if the number of messages is very large or the network is very busy. Excessive delay should be referred to the systems maintenance personnel.

K. FURTHER ACTION

When completing any one of the above tasks, the user is returned to the main menu where he may exit using 'control x' or continue for more tasks. If the user chooses to continue the program returns to the beginning, waits to be recognized again, and so on.

L. WHEN ERRORS OCCUR

The system is designed to flag most errors and allow user correction without halting execution, however should errors occur which halt the program during data communication, then the system will have to be reset. Otherwise, resetting the user terminal will allow the user to rejoin the network.

APPENDIX F

MAINTENANCE MANUAL FOR Z-100 PROGRAMS

A. XFERMAIN

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Zenith Z-100 microcomputer
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Xfermain package is the main program for the Z-100 workstations. It begins by informing the Concentrator that this particular terminal is active and then waiting to determine if the network has any files or messages waiting for it. Xfermain then presents the user with a menu of selected options: send/receive files, send/receive messages, send/receive directory, and obtain network status. Control code keystrokes then place the user in the desired environment. Xfermain contains an infinite loop that will perform the above functions until the user terminates the session with control x. Upon termination, Xfermain informs the Concentrator it is no longer active.

2. SUBROUTINES

- a. Contained: None.
- b. Called:

- Active
- Waiting
- Outconsole
- Keyin
- Sendfile
- Receivefile
- Talking
- Listening
- Whos_there
- Receive_dir
- Present_dir
- Recv_bulletin
- Clearscrn
- Off

3. COMMENTS

Xfermain is placed on all terminals of the network, except #24, the Bulletin board, and is invoked by typing the command "xfermain".

B. XFERFILE

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Zenith Z-100 microcomputer
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Xferfile package controls the sending and receiving of files from the Z-100 workstations. The user is prompted for the disk drive and file name to send or receive. The package parses and capitalizes the input into eight character filenames and three character file types, in order to conform with the requirements of CP/M-86. When the input has been confirmed by the user, Xferfile either opens an existing file or creates a new one using the file control blocks (FCBs) described in Chapter IV. Files are read and sent or received and written in 128 byte blocks. The sending and receiving processes coordinate with each other and mutually come to a halt when the processes are finished. Xferfile returns to Xfermain after each instance of file transfer.

2. SUBROUTINES

a. Sendfile

- (1) Type: Procedure
- (2) Purpose: To send a file from one terminal to another terminal or to all active terminals in the network.
- (3) Description of Parameters: None
- (4) Subroutines Called:
 - Clearscrn
 - Reset_disk
 - Drive_select
 - Parse_cap
 - Outconsole
 - Keyin
 - Open_file
 - Set_DMA
 - Enter_machine
 - Set_up
 - Read_seq
 - Yes
 - No
 - Send_block
 - Close_file
- (5) Process Description:

Sendfile controls the sending of data from a file to the receiving terminal(s). The user specifies the disk, the file name, and the file type and Send_file creates a file control block (FCB). Then the user specifies the destination terminal(s) and a connection is established. The file specified by the FCB is opened by utilizing CP/M-86 function call

#15 and data is read from the file into a data structure located at the specified direct memory address (DMA) in sequential 128 byte records by utilizing CP/M-86 function call #20. Sendfile tells the user if either an inappropriate file name or type is used, if the file specified is already open, or if the specified file cannot be found on the specified disk. If the receiver is active, the data structure containing the 128 byte record is then transmitted. Sendfile checks after each sequential read to determine if end of file has been reached and sends a yes or a no code accordingly. After the transmission has been completed, the file is closed.

b. Receivefile

(1) Type: Procedure

(2) Purpose: To receive and store a file from a sending terminal.

(3) Description of Parameters: None

(4) Subroutines Called:

Clearscrn
Reset_disk
Drive_select
Parse_cap
Outconsole
Keyin
Delete_file
Create_file
Set_DMA
Endfile
Write_seq
Recv_block
Close_file
Put_str
Put_int

(5) Process Description:

Receivefile controls the reception of file data from a sending terminal. The user specifies the disk, the file name, and the file type to store the data and a file control block (FCB) is created. The file specified by the FCB is first deleted using CP/M-86 function call #19 to ensure no duplication occurs and then created by utilizing function call #22. 128 bytes of data is received and stored in a data structure located at the specified direct memory address (DMA). The data is written to the file using function call #21 and the sender is told to send the next 128 bytes of data. Receivefile checks after each block of data is received to determine if end of file has occurred. Receivefile tells the user if either an inappropriate file name or type is used, if directory space is unavailable for the initial filename, if directory space is unavailable for new extents of an existing entry, or if disk space is full. After the

reception has been completed, the file is closed and the number of bytes received is displayed.

c. Parse_cap

(1) Type: Procedure

(2) Purpose: To parse the file name and file type for invalid characters and to capitalize both to conform to CP/M-86 protocol.

(3) Description of Parameters: A value of type fcb indicating the FCB data structure is one output parameter. A value of type Integer indicating the file name length is the other output parameter.

(4) Subroutines Called:

Outconsole

Keyin

(5) Process Description:

Parse_cap controls the creation of the user specified file name and file type. The user's input is accepted and displayed. Invalid characters are flagged and the input minus the invalid character is redisplayed for continued input. Parse_cap then capitalizes the input and stores it in the appropriate fields of FCB.

C. MESSAGES

1. CONFIGURATION

a. Language - JANUS/Ada

b. Compiler Version - 1.47

c. Linker Version - 1.47

d. Target Hardware - Zenith Z-100 microcomputer

e. Operating System - CP/M-86 (version 1.14)

f. Package description:

The Messages package controls the sending and receiving of messages from the Z-100 workstations. A maximum message size of 1600 keystrokes (including error correction) organized in 20 lines of 80 each is implemented. The user types control z to end the message and control s to send it. If the user desires to retype the message entering any character other than control s will erase the first message. After input is confirmed, the message is transmitted and received as a single block of data. The sending and receiving processes coordinate with each other and mutually come to a halt when the processes are finished. Messages returns to Xfermain after each instance of message transfer.

2. SUBROUTINES

a. Talking

(1) Type: Procedure

(2) Purpose: To send a message to one or all of the terminals currently in the network.

(3) Description of Parameters: None

(4) Subroutines Called:

Clearscrn
Outconsole
Keyin
Enter_machine
Setup
Send_block
Yes

(5) Process Description:

Talking controls the transmission of message data to receiving terminal(s). The user is prompted to begin typing the message which is displayed simultaneously exactly as typed. Talking then prompts the user for the destination terminal(s) and, after establishing connection with the receiver(s), transmits the message as a single block of data. Messages sent to destination terminal #24 are routed to the bulletin board. Talking indicates end of message by transmitting a sequence of four end of message codes.

b. Listening

(1) Type: Procedure

(2) Purpose: To receive a message from a sending terminal.

(3) Description of Parameters: None

(4) Subroutines Called:

Clearscrn
Outconsole
Keyin
Endmsg
Recv_block
Put_int

(5) Process Description:

Listening controls the reception of message data from a sending terminal. The message is received as a single block of data and terminated when a sequence of four end of message codes is received. The message is then displayed exactly as the sender typed it along with the number of bytes received.

D. DIRECTORY

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Zenith Z-100 microcomputer
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Directory package controls the sending and receiving of directory information from the Z-100 workstations. A FCB is created with question marks (?) in each character of the file name and type. This serves as a wild card and en-

sures that the entire directory will be sent. Directory entries are sent or received in 128 byte blocks. The sending and receiving processes coordinate with each other and mutually come to a halt when the processes are finished. Directory returns to Xfermain after each instance of directory transfer.

2. SUBROUTINES

a. Present_dir

- (1) Type: Procedure
- (2) Purpose: To send a directory from one terminal to another terminal or to all active terminals in the network.
- (3) Description of Parameters: None
- (4) Subroutines Called:

- Clearscrn
- Reset_disk
- Drive_select
- Outconsole
- Keyin
- Enter_machine
- Set_up
- Set_DMA
- Driveout
- Search_first
- Send_string
- Send_dir
- Search_next
- End_block
- Yes
- No
- Put_str

(5) Process Description:

Present_dir controls sending of data from a directory to the receiving terminal(s). The user specifies the disk and a file control block (FCB) is created with the wildcard filename and type (????????.???). Then the user specifies destination terminal(s) and, if they are active, a connection is established. The directory is searched for the first match to the FCB by utilizing CP/M-86 function call #17 and the directory information is placed into a data structure located at the specified direct memory address (DMA) in 128 byte records. An offset is computed to the unique match within this record. Present_dir transmits the 16 byte match to the receiving terminal(s). Function call #18 is used to obtain all subsequent matches. Present_dir transmits a total of eight 16 byte segments before transmitting the end of block code, so the receiving terminal(s) receive a full, contiguous 128 byte block. Additionally, Present_dir indicates end of directory by sending yes or no codes with each 128 bytes. The user is told if there are no files on a selected disk and a message stating such is sent to the receiving terminal(s).

b. Receive_dir

- (1) Type: Procedure
- (2) Purpose: To receive and store in a file the directory from a sending terminal.
- (3) Description of Parameters: None
- (4) Subroutines Called:
 - Clearscrn
 - Reset_disk
 - Drive_select
 - Parse_cap
 - Outconsole
 - Keyin
 - Delete_file
 - Create_file
 - Set_DMA
 - Endfile
 - Write_seq
 - Recv_block
 - Drivein
 - Close_file

(5) Process Description:

Receive_dir controls the reception of directory data from a sending terminal. The user specifies the disk, the file name, and the file type to store the data and a file control block (FCB) is created. The file specified by the FCB is first deleted using CP/M-86 function call #19 to ensure no duplication occurs and then created by utilizing function call #22. 128 bytes of data is received and stored in a data structure located at the specified direct memory address (DMA). Each 128 bytes of directory data is displayed and the user is given the option of storing the information in the file created. The data is written to the file using function call #21 and the sender is told to transmit the next 128 bytes of data. Receive_dir checks after each block of data is received to determine if end of directory has occurred. Receive_dir tells the user if either an inappropriate file name or type is used, if directory space is unavailable for the initial filename, if directory space is unavailable for new extents of an existing entry, or if disk space is full. After directory reception has been completed, the file is closed.

F. WHO

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Zenith Z-100 microcomputer
- e. Operating System - CP/M-86 (version 1.14)

f. Package description:

The Who package controls the inquiry for and reception of net status; which machines are currently active in the network.

2. SUBROUTINES

a. Whos_there

(1) Type: Procedure

(2) Purpose: To request and receive net status information.

(3) Description of Parameters: None

(4) Subroutines Called:

Clearscrn

Recv_block

Enter_machine

Setup

Put_int

(5) Process Description:

Whos_there prompts the user to enter his terminal number for both the source and destination terminals. After a connection has been established, the net status information from the Concentrator is received and displayed.

G. BULLBRD

1. CONFIGURATION

a. Language - JANUS/Ada

b. Compiler Version - 1.47

c. Linker Version - 1.47

d. Target Hardware - Zenith Z-100 microcomputer

e. Operating System - CP/M-86 (version 1.14)

f. Package description:

The Bullbrd package controls the inquiry for receiving the current messages from the bulletin board and storing them on file.

2. SUBROUTINES

a. Recv_bulletin

(1) Type: Procedure

(2) Purpose: To receive bulletin board information.

(3) Description of Parameters: None.

(4) Subroutines Called:

Clearscrn

Enter_machine

Setup

Receivefile

Keyin

(5) Process Description:

Recv_bulletin prompts the user to enter #24 for the destination terminal. Then, if the bulletin board (terminal #24) is active, Recv_bulletin establishes a connection. It calls Receivefile which handles the actual file transfer

of the data from the bulletin board and stores it in a user specified file. Error messages are displayed if either an inappropriate file name or type is used, if directory space is unavailable for the initial filename, if directory space is unavailable for new extents of an existing entry, or if disk space is full. After reception of the bulletin board data has been completed, the file is closed.

H. BULLETIN

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Zenith Z-100 microcomputer
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

Bulletin is the package that implements the network bulletin board. It controls the reception of individual messages destined for the bulletin board and the transmission in 128 byte blocks suitable for file transfer of all current messages at a given time. Messages are received in a single block. The bulletin board has the capacity of twenty messages of 1600 bytes each. When the capacity is exceeded, the first one in is the first one out. Messages are stored as an array of records with fields for the message and its length.

2. SUBROUTINES

- a. Contained: None.
- b. Called:
 - Clearscrn
 - Active
 - Waiting
 - Recv_block
 - Endmsg
 - Send_block
 - No
 - Yes

3. COMMENTS

The network bulletin board is 'hard wired' into port #24. It is invoked by typing the command "bulletin". A message is displayed stating that this terminal is the network bulletin board. The program loops endlessly waiting for requests to receive messages or send current message inventory. If another terminal at another port is desired to be the network bulletin board, the package Poll must be changed to reflect the new port. (see Appendix C.) There can be only one bulletin board active at a time.

I. MYUTIL

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Zenith Z-100 microcomputer
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Myutil package contains various utility programs in JANUS/Ada.

2. SUBROUTINES

a. Put_int

- (1) Type: Procedure
- (2) Purpose: To display integers.
- (3) Description of Parameters: A value of type integer to be displayed is the input parameter.
- (4) Subroutines Called:
My_put
- (5) Process Description:
Put_int takes the input parameter and determines its sign. Then Put_int strips off each digit, starting from the left and removing leading zeros, and displays it.

b. Clearscrn

- (1) Type: Procedure
- (2) Purpose: To clear the display screen
- (3) Description of Parameters: None.
- (4) Subroutines Called:
Outconsole
- (5) Process Description:
Clearscrn outputs the CP/M-86 clear screen codes.

c. Enter_machine

- (1) Type: Procedure
- (2) Purpose: To get the user's input of source and destination machines.
- (3) Description of Parameters: A value of type Integer indicating the source and destination machines are the output parameters.
- (4) Subroutines Called:
Outconsole
Keyin
- (5) Process Description:
Enter_machine prompts the user for input and then displays it for confirmation. The keyboard input is converted to Integer values which are assigned to the output parameters.

d. Drive_select
 (1) Type: Procedure
 (2) Purpose: To get the user's selection of disk drive.
 (3) Description of Parameters: A value of type byte indicating the disk drive selection is the output parameter.
 (4) Subroutines Called:
 Outconsole
 Keyin
 Select_drive
 (5) Process Description:
 Drive_select prompts the user for input and then displays it for confirmation. Lower case and upper case inputs are treated the same. The appropriate parameter is then passed to the CP/M-86 function call #14, which selects the drive. The drive selection is then returned as an output parameter.

H. MYASMLIB

1. CONFIGURATION

- a. Language - JANUS/Assembler
- b. Compiler Version - 1.50
- c. Linker Version - 1.50
- d. Target Hardware - Zenith Z-100 microcomputer
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Myasmlib package contains the library of assembly language subroutines for the Z-100 workstations.

2. COMMENTS

a. JANUS/Ada parameters for JANUS/Assembler modules are placed on the stack at subroutine call with the last parameter closest to the top and the return address on the very top. Discrete values are passed for parameters of type IN and the address of the parameter is passed for types OUT and IN OUT. Upon return to the calling program OUT and IN OUT parameters are removed from the stack along with the return address.

b. The following subroutines involve input and output to other terminals via the modem port (J2):

```
Send_block
Yes
No
Recv_block
Endfile
Active
Waiting
Setup
Endmsg
End_block
```

Send_string
Send_dir
Driveout
Drivein
Off

The method of transmission used involves an immediate echo checking procedure. The sending subroutine transmits bytes of data one at a time. The receiving subroutine receives the data bytes and echos each one immediately upon reception. The sending subroutine compares the echo with the transmitted data and checks for error. If an error is detected, the sending subroutine either simply retransmits or sends an error code to tell the receiving subroutine that the data previously received (and processed) was in error, followed by the retransmitted data. All receiving subroutines contain a finite waiting time after the last data was received to ensure that the final echo was received properly.

3. SUBROUTINES

a. Create_file

(1) Type: Procedure

(2) Purpose: To create files specified by the FCB.

(3) Description of Parameters: A value of type Integer containing the FCB address is the input parameter. A value of type Integer indicating the result of the CP/M-86 function call is the output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Create_file implements the CP/M-86 function call #22. It creates (and opens) the file specified by the FCB. It returns a 0, 1, 2, or 3 if the operation was successful and 255 (0FFh) if no more directory space is available.

b. Close_file

(1) Type: Procedure

(2) Purpose: To close files specified by the FCB.

(3) Description of Parameters: A value of type Integer containing the FCB address is the input parameter. A value of type Integer indicating the result of the CP/M-86 function call is the output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Close_file implements the CP/M-86 function call #16. It closes the file specified by the FCB. It returns a 0, 1, 2, or 3 if the operation was successful and 255 (0FFh) if the file could not be found.

c. Oper_file

- (1) Type: Procedure
- (2) Purpose: To open files specified by the FCB.
- (3) Description of Parameters: A value of type Integer containing the FCB address is the input parameter. A value of type Integer indicating the result of the CP/M-86 function call is the output parameter.
- (4) Subroutines Called: N/A.
- (5) Process Description:

Open_file implements the CP/M-86 function call #15. It opens the file specified by the FCB. It returns a 0, 1, 2, or 3 if the operation was successful and 255 (0FFh) if the file could not be found.

d. Read_seq

- (1) Type: Procedure
- (2) Purpose: To read data from an open file specified by the FCB.
- (3) Description of Parameters: A value of type Integer containing the FCB address is the input parameter. A value of type Integer indicating the result of the CP/M-86 function call is the output parameter.
- (4) Subroutines Called: N/A.
- (5) Process Description:

Read_seq implements the CP/M-86 function call #20. It reads sequential 128 byte records from an open file specified by the FCB into memory at the current DMA. It returns a 0 if the operation was successful and a 1 if no data exists at the next record position. Normally this indicates end of file.

e. Write_seq

- (1) Type: Procedure
- (2) Purpose: To write data to an open file specified by the FCB.
- (3) Description of Parameters: A value of type Integer containing the FCB address is the input parameter. A value of type Integer indicating the result of the CP/M-86 function call is the output parameter.
- (4) Subroutines Called: N/A.
- (5) Process Description:

Write_seq implements the CP/M-86 function call #21. It writes sequential 128 byte records to an open file specified by the FCB from memory at the current DMA. It returns a 0 if the operation was successful and a 1 if there is no more space in the directory for a new extent entry required when the file is larger than 16K (or a multiple of 16K), or a 2 if there is no more space on the disk for new data records.

f. Set_DMA

(1) Type: Procedure

(2) Purpose: To specify the Direct Memory Address (DMA).

(3) Description of Parameters: A value of type Integer containing the DMA address is the input parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Set_DMA implements the CP/M-86 function call #26. It sets the DMA to the value of the input parameter, which is normally the address of a specific data structure.

g. Delete_file

(1) Type: Procedure

(2) Purpose: To delete a file specified by the FCB.

(3) Description of Parameters: A value of type Integer containing the FCB address is the input parameter. A value of type Integer indicating the result of the CP/M-86 function call is the output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Delete_file implements the CP/M-86 function call #19. It deletes the file specified by the FCB. It returns a 0 if the operation was successful and 255 (0FFh) if the file could not be found.

h. Select_disk

(1) Type: Procedure

(2) Purpose: To select a specified disk drive.

(3) Description of Parameters: A value of type Integer containing the selected disk drive is the input parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Select_disk implements the CP/M-86 function call #14. It designates the selected disk (0 = A, 1 = B, etc.) as the default drive for subsequent disk operations.

i. Reset_disk

(1) Type: Procedure

(2) Purpose: To reset all disk drive systems.

(3) Description of Parameters: None.

(4) Subroutines Called: N/A.

(5) Process Description:

Reset_disk implements the CP/M-86 function call #13. It restores the file system to reset state where all drives are set to read/write and A is the default drive for subsequent disk operations.

j. Keyin

(1) Type: Procedure

(2) Purpose: To obtain input from the keyboard.

(3) Description of Parameters: A value of type Byte obtained from the keyboard is the output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Keyin implements the CP/M-86 function call #06. It loops infinitely until a key is pressed and then the character obtained is returned as the output parameter.

k. Outconsole

(1) Type: Procedure

(2) Purpose: To display output to the console device.

(3) Description of Parameters: A value of type Byte to be displayed is the input parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Outconsole implements the CP/M-86 function call #02.

l. Send_block

(1) Type: Procedure

(2) Purpose: To send a block of data to another terminal via the modem port.

(3) Description of Parameters: A value of type Integer indicating the address of the data structure to be sent is one input parameter. A value of the type Integer indicating the size of the data structure is the other input parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Send_block sends a block of data out the modem port (J2) sequentially one byte at a time, decrementing the size of the data block until it equals zero. Then it transmits a sequence of four end of block codes (0FFh) to indicate that end of block has been reached. Any data structure may be sent using this procedure.

m. Yes

(1) Type: Procedure

(2) Purpose: To indicate to the receiving terminal(s) that an end of process has been reached.

(3) Description of Parameters: None.

(4) Subroutines Called: N/A.

(5) Process Description:

Yes sends out a sequence of four end of process codes (0F1h) when a particular process is finished.

n. No
 (1) Type: Procedure
 (2) Purpose: To indicate to the receiving terminal(s) that a process is still ongoing.
 (3) Description of Parameters: None.
 (4) Subroutines Called: N/A.
 (5) Process Description:
 No sends out a single no code (6Eh) to indicate that a process is not finished.

o. Recv_block
 (1) Type: Procedure
 (2) Purpose: To receive a block of data from another machine via the modem port.
 (3) Description of Parameters: A value of type Integer indicating the address of the data structure in which the received data will be stored is the input parameter. A value of the type Integer indicating the amount of data received is the output parameter.
 (4) Subroutines Called: N/A.
 (5) Process Description:
 Recv_block receives a block of data from the modem port (J2) sequentially one byte at a time, incrementing the size of the data block until a sequence of four end of block codes (0FFh) is received indicating that end of block has been reached. Any data structure may be received using this procedure.

p. Endfile
 (1) Type: Procedure
 (2) Purpose: To determine whether or not a file or directory transfer process has finished
 (3) Description of Parameters: A value of the type Boolean indicating finish or not is the output parameter.
 (4) Subroutines Called: N/A.
 (5) Process Description:
 Endfile waits to receive either a single no code (6Eh) or a sequence of four end of process codes (0F1h). If a no code is received the value false is returned to the output parameter, if a sequence of four end of process codes is received a value of true is returned.

q. Active
 (1) Type: Procedure
 (2) Purpose: To indicate to the Concentrator that a particular terminal is in the network.
 (3) Description of Parameters: None.
 (4) Subroutines Called: N/A.
 (5) Process Description:
 Active sends out an active code (0D0h) when the terminal is ready to communicate with the network.

r. Waiting

- (1) Type: Procedure
- (2) Purpose: To receive the status the Concentrator has for an active terminal.
- (3) Description of Parameters: A value of type byte indicating the status.
- (4) Subroutines Called: N/A.
- (5) Process Description:
Waiting receives the status from the Concentrator that a terminal's active code prompted. A 0 indicates nothing waiting, a 1 indicates file waiting, a 2 indicates message waiting, and a 3 indicates that the inactive receiving terminal to which this terminal had previously tried to send is now active.

s. Setup

- (1) Type: Procedure
- (2) Purpose: To establish a connection with another terminal via the Concentrator.
- (3) Description of Parameters: A value of type Integer indicating the address of the connection data structure. A value of the type Boolean indicating the result of the connection set up attempt is the output variable.
- (4) Subroutines Called: N/A.
- (5) Process Description:
Setup transmits to the Concentrator the connection data structure for the purposes of establishing a connection with another terminal. The connection data structure consists of destination field for the destination terminal(s), a source field for the source terminal, and a process field for the process to be accomplished. Setup sends out a sequence of four end of block codes (0FFh) to indicate the end of the data structure. It then waits to determine the result of the connection set up attempt. If the connection was successful, send_ready is set to true. If it was not because the destination was inactive, then send_ready is set to false.

t. Myput

- (1) Type: Procedure
- (2) Purpose: To display integers.
- (3) Description of Parameters: A value of type Integer indicating the integer to be displayed.
- (4) Subroutines Called: N/A.
- (5) Process Description:
Myput converts the integer input into its ascii equivalent and uses CP/M-86 function call #02 to display it.

u. Put_str

- (1) Type: Procedure
- (2) Purpose: To display strings.
- (3) Description of Parameters: A value of type String indicating the address of the string to be displayed.

(4) Subroutines Called: N/A.

(5) Process Description:

Put_str is passed the address of the string to be displayed. The first byte at that address is the string length. The succeeding byte are displayed using CP/M-86 function call #02 until the string length counter equals zero.

v. Endmsg

(1) Type: Procedure

(2) Purpose: To determine if end of message has occurred.

(3) Description of Parameters: None.

(4) Subroutines Called: N/A.

(5) Process Description:

Endmsg waits until a sequence of four end of message codes (0F1h) is received.

w. Search_first

(1) Type: Procedure

(2) Purpose: To search for the first directory match.

(3) Description of Parameters: A value of the type Integer indicting the buffer address for the directory record is one input parameter. A value of the type Integer indicting the FCB address is the other input parameter. A value of the type Integer indicting the result of the function is one output parameter. A value of the type Integer indicting the location of the matched directory entry is the other output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Search_first implements CP/M-86 function call #17. It searches the directory of the specified drive for the first match of the file name and type of the specified FCB. When a successful match is found, Search_first places the 128 byte record containing the matched directory entry and returns an offset code (0, 1, 2, or 3) that specifies the exact location of the entry within the record using the formula: location of entry = (offset * 32) + DMA. If a match cannot be found, then Search_first returns 255 (0FFh).

x. Search_next

(1) Type: Procedure

(2) Purpose: To search for the next directory match.

(3) Description of Parameters: A value of the type Integer indicting the buffer address for the directory record is one input parameter. A value of the type Integer indicting the FCB address is the other input parameter. A value of the type Integer indicting the result of the function is one output parameter. A value of the type Integer

indicting the location of the matched directory entry is the other output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Search_next implements CP/M-86 function call #18. It searches the directory of the specified drive for the next match of the file name and type of the specified FCB. When a successful match is found, Search_first places the 128 byte record containing the matched directory entry and returns an offset code (0, 1, 2, or 3) that specifies the exact location of the entry within the record using the formula: location of entry = (offset * 32) + DMA. If a match cannot be found, then Search_first returns 255 (0FFh).

y. End_block

(1) Type: Procedure

(2) Purpose: To indicate end of block during directory transfer.

(3) Description of Parameters: None.

(4) Subroutines Called: N/A.

(5) Process Description:

End_block transmits a sequence of four end of block codes (0FFh) to indicate end of block during directory transfers.

z. Send_string

(1) Type: Procedure

(2) Purpose: To transmit strings.

(3) Description of Parameters: A value of type String indicating the address of the string to be output is the input parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Send_string is passed the address of the string to be transmitted. The first byte of the input parameter is the length of the string. Send_string transmits the succeeding bytes one at a time out the modem port (J2) until the string length counter equals zero.

aa. Send_dir

(1) Type: Procedure

(2) Purpose: To transmit matched directory entries.

(3) Description of Parameters: A value of type Integer indicating the address of the matched directory to be output is one input parameter. A value of the type Integer indicating the size of the directory entry to be transmitted is the other input parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Send_dir transmits the bytes of the matched directory entry sequentially, one byte at a time, via the modem port (J2) until the directory length counter equals zero.

bb. Driveout

- (1) Type: Procedure
- (2) Purpose: To transmit the disk drive used in a directory transfer.
- (3) Description of Parameters: A value of type Byte indicating the specified drive to be output is the input parameter.
- (4) Subroutines Called: N/A.
- (5) Process Description:
Driveout transmits the byte representing the specified drive via the modem port (J2).

cc. Drivein

- (1) Type: Procedure
- (2) Purpose: To receive the disk drive used in a directory transfer.
- (3) Description of Parameters: A value of type Byte indicating the specified drive received is the output parameter.
- (4) Subroutines Called: N/A.
- (5) Process Description:
Drivein receives the byte representing the specified drive via the modem port (J2).

dd. Off

- (1) Type: Procedure
- (2) Purpose: To inform the Concentrator that a terminal is no longer active.
- (3) Description of Parameters: None.
- (4) Subroutines Called: N/A.
- (5) Process Description:
Off transmits the off code (0Fh) via the modem port (J2).

J. NAMES

1. CONFIGURATION

APPENDIX C

MAINTENANCE MANUAL FOR CONCENTRATOR PROGRAMS

A. POLL

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Intel 86/12A SBC
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Poll package is the main program for the Concentrator acting as a network switchboard. It contains an infinite loop that polls each one of 23 ports (bypassing port #24 which is designated as the bulletin board port and is never polled) continuously. Poll controls the satisfying of requests from the Z-100 workstations and the storing of those requests in a FIFO queue that cannot be satisfied. For each port Poll checks the queue for waiting processes. If there is a process waiting, Poll will satisfy the waiting process and then attempt to satisfy the polled port's original request. If not, Poll will immediately attempt to satisfy the polled port's request. Poll is responsible for decoding each workstation's request and establishing the proper path between sender and receiver(s). It is also responsible for maintaining the net status; the list of all currently active ports, and transmitting it to workstations requesting it.

2. SUBROUTINES

a. Convert

(1) Type: Procedure

(2) Purpose: To convert the byte information received from the Z-100 workstations concerning source and destination terminals into their integer physical addresses.

(3) Description of Parameters: A value of type integer indicating the index position in the queue of the current process_status record is the input variable.

(4) Subroutines Called: None

(5) Process Description:

Convert is two large case statements which translate the bytes received from the workstations into the proper integer physical addresses for each port.

b. Poll calls the following subroutines:

Check_port
Check_queue
Connect
Convert
Xfer
Concxfer

No_xfer
Broadcast
Net_stat
Queue_status

3. COMMENTS

Poll is resident in the Concentrator and is invoked by typing the command "poll". It will not function properly if all three 8538 BLC expansion boards are not installed.

To change the port number of the bulletin board, the polling sequence must be changed to bypass the new bulletin board port and the automatic routing routines that route bulletin board requests to the predesignated port must be changed accordingly. Additionally the value of 'bullport' in the procedure Broadcast must be changed.

To expand the system for greater numbers of terminals, add the appropriate number of expansion boards and change the following constants: 'boardno', 'machno', 'maxque', and the procedure Convert which contains the physical addresses. Additionally, the value of 'boardnum' must be changed in the procedure Broadcast.

B. CONUTIL

1. CONFIGURATION

- a. Language - JANUS/Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Intel 86/12A SBC
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Concutil package contains utility programs for the Concentrator.

2. SUBROUTINES

a. Check_queue

(1) Type: Procedure

(2) Purpose: To check the queue for waiting processes.

(3) Description of Parameters: A value of type Integer indicating the number of processes waiting in the queue is one input parameter. A value of type Integer indicating the port for whom waiting processes are being checked is the other input parameter. A value of type Integer indicating the position index of the waiting process is one output variable. A value of type Boolean indicating whether or not there are waiting processes is the other output variable.

(4) Subroutines Called:

Check_port
Queue_status

(5) Process Description:

Check_queue checks the queue for waiting processes. If there are none in the queue then false is returned. If there are processes in the queue, a check is made if they are waiting for the specified port. If not, false is returned. If there are processes in the queue and they are waiting for the specified port, their position in the queue is returned along with a value of true. Check_queue then tells the specified port what is waiting for it and tells the sender of the waiting process to resend.

b. Net_stat

(1) Type: Procedure

(2) Purpose: To decode and transmit the list of active terminals in the network to the requestor.

(3) Description of Parameters: A value of type integer indicating the port for which the net status is intended.

(4) Subroutines Called:

Send_who_block

(5) Process Description:

Net_stat controls the transmission of the list of active network terminals. Net_stat checks the data structure 'active_list' for those terminals for which true has been recorded, indicating that they are active and stores the terminal number information in the data structure 'who_list'. It is 'who_list' that is transmitted to the requestor.

C. COASMLIB

1. CONFIGURATION

a. Language - JANUS/Assembler

b. Compiler Version - 1.50

c. Linker Version - 1.50

d. Target Hardware - Intel 86/12A SBC

e. Operating System - CP/M-86 (version 1.14)

f. Package description:

The Coasmlib package contains the library of assembly language subroutines for the Concentrator.

2. COMMENTS

a. JANUS/Ada parameters for JANUS/Assembler modules are placed on the stack at subroutine call with the last parameter closest to the top and the return address on the very top. Discrete values are passed for parameters of type IN and the address of the parameter is passed for types OUT and IN OUT. Upon return to the calling program OUT and IN OUT parameters are removed from the stack along with the return address.

b. The following subroutines involve input and output:

Check_port
Connect
Queue_status
Send_who_block
Broadcast
Concxfer
Xfer
No_xfer

The method of transmission used involves an immediate echo checking procedure. The sending subroutine transmits bytes of data one at a time. The receiving subroutine receives the data bytes and echos each one immediately upon reception. The sending subroutine compares the echo with the transmitted data and checks for error. If an error is detected, the sending subroutine either simply retransmits or sends an error code to tell the receiving subroutine that the data previously received (and processed) was in error, followed by the retransmitted data. All receiving subroutines contain a finite waiting time after the last data was received to ensure that the final echo was received properly.

3. SUBROUTINES

a. Check_port

(1) Type: Procedure

(2) Purpose: To poll network ports looking for the active signal

(3) Description of Parameters: A value of type Integer containing the address of the port to be polled is the input variable. A value of type Boolean indicating the result of the poll is the output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Check_port polls the port indicated looking for the active signal (0D0h). It will poll for a finite period of time. If no signal, or the wrong signal, is found, ready is set to false. If the active signal is found, ready is set to true. Check_port is used for two purposes. It is used to initially poll ports for incoming requests (indicated by active signal) and to poll a destination port to determine if it is ready to receive.

b. Connect

(1) Type: Procedure

(2) Purpose: To receive the connection record transmitted by the sending Z-100.

(3) Description of Parameters: A value of type Integer containing the address of the port from which the connection record is to be received is the input parameter. A value of type Integer indicating the address of the data structure in which the connection record is to be stored is the output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Connect receives the connection record, sequentially, one byte at a time and stores it in the data structure indicated by the input parameter until a sequence of four finish codes (0FFh), indicating end of block, are received.

c. Queue_status

(1) Type: Procedure

(2) Purpose: To inform a polled port of the status of waiting processes in the queue.

(3) Description of Parameters: A value of type Integer containing the address of the polled port is one input parameter. A value of type Byte indicating the process waiting in the queue (or none) is the other output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Queue_status transmits to the port indicated by one input parameter the byte value of the process waiting for that port (or none).

d. Send_who_block

(1) Type: Procedure

(2) Purpose: To transmit the data structure containing the net status.

(3) Description of Parameters: A value of type Integer containing the address of the port to which the net status is destined is one input parameter. A value of type Integer indicating the address of the data structure containing the net status is another input parameter. A value of type Integer indicating the length of the data structure is the last output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Send_who_block transmits the data structure containing the net status sequentially, one byte at a time, until the length counter equals zero. Then it sends out a sequence of four finish codes (0FFh), indicating end of block.

e. Broadcast

(1) Type: Procedure

(2) Purpose: To transfer data in a broadcast mode: from one to many.

(3) Description of Parameters: A value of type Integer containing the address of the sending port is the input parameter. A value of type Byte containing the address used to store the input temporarily is the output parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Broadcast controls the transmission of data from the sending port to all receiving ports. The data is transmitted one byte at a time as rapidly as possible to all ports (bypassing the sender, and the bulletin board). The first byte is received from the sending port specified in the first input parameter. It is then sent in quick succession to all the ports beginning with the first port in the network. Broadcast increments the receiving port until all the ports are addressed and the byte is transmitted. The input is saved temporarily for error checking. Then Broadcast loops back to receive the echoes. If there are any echoes in error, that port address is saved until all the echoes have been received. Then all the addresses in error are serviced, one at a time until the error is corrected. At this point, or if there were no errors, Broadcast echoes back to the sender the received byte for the sender's error checking. If there was an error, the sender sends out an error code then the retransmitted byte and the entire process is repeated until the error is corrected. If there is no error, the next byte is transmitted to the Concentrator until a sequence of four end of process code echoes (2F1h) are received from all the receiving terminals. Broadcast waits only a finite period of time for echoes from each receiving terminal, so if a terminal is inactive, the bytes transmitted to it will be continuously overwritten. No attempt is made to bypass inactive terminals.

f. Concxfer

(1) Type: Procedure

(2) Purpose: To transfer data from a sending terminal to a single destination terminal.

(3) Description of Parameters: A value of type Integer containing the address of the sending port is one input parameter. A value of type Integer containing the address of the receiving port is the other input parameter.

(4) Subroutines Called: N/A.

(5) Process Description:

Concxfer controls the transmission of data between two terminals. The first byte is received from the sending port indicated by the first input parameter and transmitted from the receiving port indicated by the second parameter. The echo is then received from the receiver and transmitted to the sender. Concxfer performs no error checking; it merely passes data and echoes back and forth until it receives a sequence of four end of process code echoes (2F1h) from the receiver. At that point it terminates the connection.

g. Xfer

- (1) Type: Procedure
- (2) Purpose: To inform the sending port that a connection has been established.
- (3) Description of Parameters: A value of type Integer containing the address of the sending port is the input parameter.
- (4) Subroutines Called: N/A.
- (5) Process Description:
Xfer transmits to the sending port a code (01h) informing it that a connection has been established.

h. No xfer

- (1) Type: Procedure
- (2) Purpose: To inform the sending port that a connection can not be established.
- (3) Description of Parameters: A value of type Integer containing the address of the sending port is the input parameter.
- (4) Subroutines Called: N/A.
- (5) Process Description:
No xfer transmits to the sending port a code (00h) informing it that a connection can not be established.

D. CONCNAMF

1. CONFIGURATION

- a. Language - JANUS /Ada
- b. Compiler Version - 1.47
- c. Linker Version - 1.47
- d. Target Hardware - Intel 86/12A SBC
- e. Operating System - CP/M-86 (version 1.14)
- f. Package description:

The Concname specification contains the following global objects:

TYPE process_status
max_que
TYPE que
queue
resend
zero
machno
ready
active_list

GLOSSARY

1. Z-100

Z-100 is the specific model name for the micro-computers used in this network. The vendor is Zenith Data Systems.

2. SBC

SBC is an acronym for Single Board Computer. It is a configuration of VLSI (Very Large Scale Integration) circuitry on one computer board capable of performing the functions of a computer. The SBC is the driving force in the Concentrator. The vendor of the 86/12A SBC used in this thesis is Intel Corporation.

3. Concentrator

The Concentrator is the collection of hardware and software that performs the network switching functions.

4. MULTIBUS

MULTIBUS is the specific model name for the hardware that allows multiple SBC's to communicate directly with common memory.

5. Local Area Network

A Local Area Network is any network that operates exclusively within a low radius (max 50 miles) region; usually a single building or a group of buildings.

6. Workstation

A Workstation is viewed as the Z-100 microcomputer and associated peripheral devices that perform the application functions of the network.

7. Process

Processes are viewed as the transfer of files, messages, or directories between Z-100 workstations. Each process has a sending and a receiving function.

8. Communication

Communication is viewed as transmitting data and/or commands between the sending and receiving functions of a process.

9. Data Communication Channel

Data Communication Channel refers to the channel or 'pathway' used to transfer intra-process communications between Z-100 workstations.

10. Circuit Switching

Circuit Switching refers to the method of network communication whereby the entire message containing data and commands is transmitted from the sender to the receiver along a dedicated communication channel.

11. Ports

Ports are channels through which processes communicate.

12. USART

USART is an acronym for Universal Synchronous/Asynchronous Receiver/Transmitter. It is a microprocessor that provides communication interface between computers or between a computer and a peripheral device.

13. NPS

NPS is an acronym for Naval Postgraduate School, Monterey, California.
